Introducing Mini Dental Implants

Undoubtedly the lower denture presents the most difficulty for patients adjusting to dentures for the first time . Or even for experienced denture wearers. It can be frustrating as you attempt to eat certain foods, or even to speak with confidence without fear that your lower denture will begin to float in your mouth.

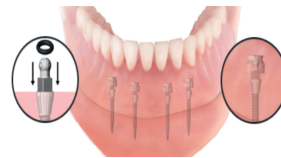

We have now a treatment procedure called a DENTURE STABILIZATION SYSTEM . Essentially it is a mini dental implant system that in most cases can be placed and attached to your lower denture . There is no need for any incision or stitches in most cases and after the healing process plus denture adjustments you will have a more secure denture, allowing you to eat and speak much more comfortably.

How are Mini Dental Implants Placed?

Placement of the mini dental implants is accomplished quickly and easily in a process performed in our dental practice. The mini dental implants are placed on our designated surgery Fridays by Dr. Safa Souzani using a precise, controlled, minimally invasive surgical technique. Mini Dental Implants are placed into the jawbone. All the denture measurements and adjustments are made with our Denture prosthesis Mr. Peter Agosta.

The heads of the implants protrude from the gum tissue and provide a strong, solid foundation for securing dentures. (upper dentures can also be secured). It is a one step procedure that involves minimally invasive surgery.

Four Lower mini implants placed in the lower jaw for stabilization of the lower Denture. Procedure can also be performed for upper denture and Single missing teeth.
